

1.

```
my_str = "The first one is the easiest!"

res = []
my_str_ = my_str.split()
first, second, third = 1, len(my_str_), 2
while first < second:
    res.append(my_str_[first])
    first += third
```

Code explanation:

We have a string, my\_str and we create an array res. We create my\_str\_, an array of strings that is split by spaces. We set ints first, second, and third to be 1, the length of my\_str\_, and 2. Then, while first is less than second, we append my\_str\_'s 'first' element and then we add the third value to first

One liner: `res = my_str.split()[1::2]`

2.

```
my_dictionary = {}
for x in range(100, 0, -3):
    if x % n == 0:
        my_dictionary[x] = f"{x} is divided by {n}.\n"
    else:
        my_dictionary[x] = f"the remainder of {x} divided by {n} is: {x % n}.\n"
print(*my_dictionary.values(), sep="")
```

This code creates a dictionary with the key being a number and the value being a string that says that the number x is divisible by n, going down from 100 by 3s.

If it is not divisible, the value is a string that says that the remainder of x divided by n is the remainder

Then, the code prints the dictionary

```
print(*{x: f"{x} is divided by {n}.\n" if x % n == 0 else f"the remainder of {x} divided by {n} is: {x % n}.\n" for x in range(100, 0, -3)}.values(), sep="")
```

3.

```
for i in range(0, max(ord('9'), ord('z'), ord('Z'))+1):
    if chr(i).isalpha() or chr(i).isdigit():
        print(f"The ASCII number {i} represent the char '{chr(i)}'")
```

This code goes from 0 to the maximum of the unicode characters for '9', 'z', 'Z' and then you add 1.

If the character of the unicode code is a letter or a number, print the ascii number i represents the character chr(i).

```
print(*(f"The ASCII number {i} represent the char '{chr(i)}'" for i in
range(max(ord('9'), ord('z'), ord('Z')) + 1) if chr(i).isalnum()),
sep="\n")
```

4.

```
list_c = [80, 121, 116, 104, 111, 110, 32, 105, 115, 32, 102, 117, 110, 33]
tmp_chr = ""
for num in list_c:
    tmp_chr += chr(num)
print(tmp_chr)
```

This code takes an array list\_c and then adds all of the character values of the unicode to string tmp\_chr and then prints it

```
print("".join(chr(num) for num in list_c))
```
